Accessible summary

The use of a standardized nursing language enhances nursing quality. The Nursing Interventions Classification (NIC) considers any treatment by nurses that improve patient outcomes.

The present study identifies nursing interventions in journal articles on adult psychiatric inpatient nursing care. These interventions are compared with the NIC entries to elucidate how well this classification covers the realities of nursing in inpatient psychiatric settings.

The NIC encompasses most interventions mentioned in the articles. Only a few interventions need to be added to the NIC classification or require a reorganization of the taxonomy.

Abstract

The successful application of the Nursing Interventions Classification (NIC) in inpatient psychiatry depends on whether the classification adequately describes nursing care in this setting. The present study aimed to identify nursing interventions mentioned in journal articles on psychiatric inpatient nursing care and to compare these with the labels, definitions and activities described in the NIC to elucidate how well the classification covers these interventions.

The MedLine, PsychInfo, Cochrane and CINAHL databases were searched for journal articles about nursing care in the adult inpatient setting. A qualitative content analysis approach was used to identify nursing interventions in the articles. About 84% of the statements (terms and definitions) are encompassed by the interventions listed by the NIC. Very few interventions need to be added to the NIC classification or necessitate a reorganization of the taxonomy. Nevertheless, the further development of the NIC will promote its use in the daily work of psychiatric nurses and enhance the quality of nursing care in the inpatient setting.

Introduction

The inpatient setting is only one part of the mental health care system, but clearly an important one (Aiyegbusi & Norton, 2009). The following four reasons justify admission to an inpatient ward: the patient or relatives are unable to perform daily self-care and need help at different times during the day; the patient is in an acute personal crisis and needs services around the clock; the situation of the patient requires compulsory measures or special treatments which can only be administered in an inpatient facility, and the patient or relatives need a temporary change of setting (Sauter et al., 2011). The nursing service provides 'around the clock service' in a safe and structured environment for this group of patients (Jordan Halter, 2009) which includes three main aspects: caring, attending, and patient advocacy (Varcarolis, 2009). The nurse interacts with patients and assists them to 1) resolve the mental, emotional, and dysfunctional aspects of life crises; 2) manage and alleviate or ease painful symptoms of mental disorders; 3) improve overall functions; and 4) decrease the personal and social consequences of mental illness, including the stigma attached to mental disorders (Holoday Worret, 2008).

As part of the professionalization of nursing care, there are ongoing efforts to document inpatient psychiatric nursing care with standardized languages. Documentation with standardized nursing languages enhances the continuity of care and improves analyses which support unit, organizational and national policy decisions to ensure quality and effectiveness (Keenan & Yakel, 2005; Keenan, Tschannen & Wesley, 2008; Müller-Staub, Needham, Odenbreit, Lavin & van Achterberg, 2007, 2008). Just et al. (2005) recommend the use of the Nursing Interventions Classification (NIC) for the documentation of nursing interventions within a standardized documentation structure and, additionally, of the NANDA International (NANDA-I) nursing diagnoses classification and of the Nursing Outcomes Classification (NOC).

The successful application of the Nursing Interventions Classification (NIC) in adult inpatient psychiatry depends on whether the classification adequately describes the reality of daily nursing care. No references were found in the literature to the suitability of the NIC to inpatient psychiatric nursing care. Therefore, as a first step, the present literature review considered this setting.

Background

The NIC includes three taxonomic levels: domains (N=7), classes (N=30) and interventions (N=542). The core of the NIC is the concept of interventions. A nursing intervention is *“any treatment, based upon clinical judgment and knowledge that a nurse performs to enhance patient / client outcomes”* (Bulechek 2008) encompassing direct and indirect patient care. Interventions may be aimed at individuals, families or the community and initiated by nurses, physicians and other healthcare providers (Bulechek 2008). Every intervention has a label name, a definition and a list of activities describing specific behaviors or actions in practical nursing work. Several activities are necessary to create and implement an intervention. Contrary to interventions, activities are not standardized. To implement an intervention, the corresponding activities have to be selected and, if necessary, modified or complemented with further activities to meet the needs of patients, families or communities as well as to individualize care (Bulechek 2008). With regard to the same intervention, the number of listed activities as well as the combination of activities can vary from patient to patient. It is essential that the modification or addition of activities is congruent with the corresponding definition of the intervention (Bulechek 2008).

Research Questions

The present study identified nursing actions described in journal articles in adult inpatient psychiatry. The nursing actions found in the literature were then assigned

to the standardized nursing interventions of the Nursing Interventions Classification (NIC). The following two research questions were formulated:

- What nursing interventions are described in publications in adult inpatient psychiatry?
- Which nursing interventions identified in the publications have already been described and included in the labels and definitions of the nursing interventions of the classification of Nursing Interventions Classification (NIC)?

Method

Search strategy

The systematic search for articles published in nursing journals included the databases MedLine, PsychInfo, Cochrane and CINAHL. Articles meeting the following inclusion criteria were eligible:

- Published between 1993 and 2008
- Published in English or German
- Addressed to psychiatric nursing or mental health nursing
- Pertaining to an inpatient setting
- Pertaining to patients with a mental illness / mental disorder aged 18 – 65 years
- Published in nursing journals or journals that explicitly address mental health nursing.

To identify the setting of the articles the following search terms were used: 'psychiatry' OR 'mental health care' AND 'inpatient'. To focus on articles addressing the practice of nurses, the terms above were linked with the following search terms combined in various ways and, if relevant, in singular and plural forms: 'nursing',

'care', 'caring', 'nursing interventions', 'nursing action', 'nursing activity', 'nursing concept', 'nursing phenomena', 'actual health problem', 'potential health problem', 'acute health problem', 'chronic health problem', 'actual life process', 'potential life process', 'life process', 'clinical judgment', 'behavior', 'perception', 'clinical judgment'. The search was stopped when no new articles were found.

Methodology and Data Analysis

The articles identified were analyzed by using a qualitative content analysis approach. This approach is suitable for analyzing and categorizing datasets from any kind of communication according to empirical or theoretical criteria (Mayring, 2010). The content analysis focused on issues related to the NIC definition of nursing intervention: *"Any treatment, based upon clinical judgment and knowledge that a nurse performs to enhance patient / client outcomes"* (Bulechek et al. 2008). Initially, the first author read and reread the articles. Passages mentioning nursing actions accomplished by nurses were identified. Secondly, the first author isolated each individual action and created a list of terms regarding the contexts, aims and intentions of the actions in the articles. Further, text passages specifying the actions were also isolated and added to the corresponding term. The listed actions feature two levels of abstraction. On the one hand, there are actions on the abstraction level of the standardised NIC interventions that describe treatment performed by nurses. On the other, there are actions on the level of NIC activities describing a specific behavior or intervention.

In a next step, the author compared the actions extracted from the articles with those in the Nursing Interventions Classification (NIC): Actions at the abstraction level of interventions were assigned to interventions defined by the NIC; actions on the abstraction level of activities were assigned to the list of activities of corresponding NIC interventions considering the contexts, aims and intentions

described in the text. These identified interventions were also added to the list of interventions found on the abstraction level of interventions.

In about one-third of the isolated actions, it was not possible to assign a distinct mapping or there was a lack of an appropriate NIC intervention. For each action of this type, the first, second and third author suggested, independently of each other, an allocation to an existing or a newly created intervention. Further, the authors discussed their resulting lists term by term until a consensus was reached - again taking contexts, aims, definitions, and intentions into consideration.

Results

The initial search generated 484 abstracts. After a first review, 408 abstracts were excluded because they did not meet the inclusion criteria: most of the articles did not address inpatient settings and/or psychiatric/mental health nursing. The remaining 76 articles were studied in detail; 31 papers included statements of nursing actions; 15 publications presented qualitative surveys, nine reported quantitative studies and three a combination of both approaches. Additionally, two papers were literature reviews, one a discussion paper including vignettes and one a description of an instrument. The details about the articles in Table 1 include research questions and sample sizes. The most frequent sources of studies were Sweden (9) and the United Kingdom (8).

Table :1 Overview of papers analyzed in the study

Statements listed in the Nursing Interventions Classification (NIC)

The articles included 111 statements (terms, definitions) that could be allocated to 45 different NIC interventions, which represented 16 of 30 NIC classes and all 7 NIC domains. Table 2 lists these terms and descriptions found in the articles, as well as their assignment to the corresponding NIC interventions, classes and domains. Some interventions were listed in several NIC domains or classes, resulting in differences between the numbers of identified statements in the studies and the interventions contained in NIC domains and classes.

Table 2: Overview of the statements listed in the Classification NIC

| NIC Intervention / Code (Domains, Classes) | N | Actions: Text passages specifying the actions |
|---|---|---|
| Medication Administration 2300; 2 (H) | 9 | Medication administration / administration of medication / the administration of prescribed medication / administration of medication / to inform the patient about the main effects of medication, medication side-effects / discussions about medication side-effect with service users / evaluate which medication is the most appropriate for the current situation / make the best decision about whether to administer a p.r.n medication / medication administration: <i>“Medication administration is more than selecting the right medicine and administering the medicine to the right patient; it is also checking on whether the medication has been ingested and monitoring desirable and undesirable effects... Medication Administration was described as a ritual, initiated by selecting the right medicine, followed by giving the patients the medicines, and ending by recording the administration”</i> (Haglund et al. 2004). |
| Environmental Management: Safety 6486; 4 (V) | 7 | To create a secure environment for the patient / to establish and maintain a safe milieu / the maintenance of a safe environment / removal of environmental dangers / creating a secure environment: <i>“The nurse gives time and attention to the patient, which may entail just being and sitting silently with her”</i> (Engqvist et al. 2007) / provide a safe environment: <i>“The degree to which the psychiatric inpatient environment qualifies as safe is directly dependent on factors such as the methods and tools used to monitor risk for self-harm. For example, psychiatric units have long attempted to assess opportunity risk”</i> (Temkin & Crotty, 2004) / Protecting patients from dangerous items: <i>“Routine safety searches (once per week), irregular searches, detailed safety searches (every shift) and intimate safety searches (body safety searches) (Sun et al. 2005).</i> |
| Surveillance: Safety 6654; 4 (V) | 7 | The performance and documentation of special observations / monitoring patients on suicide or homicide precautions / |

Domains

Most interventions were reflected in the domains *“Safety: Care that supports protection against harm”* (N: 44), *“Behavioral: Care that supports psychosocial functioning and facilitates lifestyle changes”* (N: 37) and *“Health System: Care that supports effective use of the health care delivery system”* (N: 24). The domains *“Physiological: Complex: Care that supports homeostatic regulation”* (N: 11), *“Community: Care that supports the health of the community”* (N: 6) as well as the domains *“Physiological: Basic: Care that supports physical functioning”* (N: 3) and *“Family: Care that supports the family”* (N: 3) were also represented.

Classes

In-depth analysis showed variations of incidence at the level of classes in contrast to domains. The domains with the most nominations did not necessarily contain the classes with the most frequently listed interventions. In some cases, the incidence of classes varied with the incidence of the domains. The class *“Risk Management: Intervention to initiate risk-reduction activities and continue monitoring risks over time”* (N: 40) was far more frequently identified than other classes. This class is involved in the most frequently named domain and responsible for its rank in the order of precedence. The second most frequently identified class was *“Health System Mediation: Intervention to facilitate the interface between patient/family and the health care system”* (N: 18). This class is listed in the domain *“Health System”* that contained the third most frequent references. The class *“Coping Assistance: Interventions to assist another to build on own strengths, to adapt to a change in function, or achieve a higher level of function”* (N: 13) presented the third most frequently identified class. Because there were five other classes, e.g. *“Patient Education: Interventions to facilitate learning”* (N: 11; 4th position) and *“Behavior Therapy: Intervention to reinforce or promote desirable behaviors or alter undesirable behaviors”* (N: 6; 5th position), the

corresponding domain *“Behavioral”* appeared as the second most frequently identified domain.

The class *“Drug Management: Intervention to facilitate desired effects of pharmacological agents”* (N: 11) – the fourth most frequently identified class beside *“Patient Education”* – was the only class that registered statements from articles in the domain of *“Physiological: Complex”*, which is the largest domain in NIC. Beside the class *“Behavior Therapy”* mentioned above, there was another class in 5th position: *“Community Health Promotion: Interventions that promote the health of the whole community”*. The remaining 23 classes contained less than five or no mentions.

Interventions

The NIC intervention *“Medication Administration”* describes nursing tasks related to medication; nine actions in the articles were analyzed as describing such interventions. Seven actions found in the articles were allocated to the NIC interventions *“Environmental Management: Safety”* and *“Surveillance: Safety”*. The main focus of both interventions is safety, on the one hand by monitoring and manipulating the physical environment, and on the other by collecting and analyzing information about the patient and his or her environment. Six actions were related to each of the three NIC interventions: *“Case Management”* that coordinates care and advocates for individuals or groups across settings; *“Chemical Restraint”* that describes the handling of psychotropic agents to control extreme behavior; and *Discharge Planning* that prepares the patient to move on from a particular setting. Five actions fell into the category of the NIC interventions *“Presence”*. This intervention characterizes the physical and psychological presence of nurses in the care of patients. The NIC interventions *“Surveillance”* and *“Teaching: Disease Process”* both reflect four actions. The first intervention describes the acquisition and handling of patient data for clinical decision-making,

the second intervention delineates the procedure of teaching patients to understand information relating to their disease.

There were six NIC interventions that were addressed by three actions each: *“Admission Care”*, *“Physical Restraint”*, and *“Risk Identification”*, as well as *“Substance Use Treatment”*, *“Suicide Prevention”*, and *“Teaching: Procedure / Treatment”*. *“Admission Care”* is a description of the regular care at the moment of entry into a care facility. *“Physical Restraint”* addresses the procedure of mechanical restraining, and *“Risk Identification”* analyzes potential risk factors for a patient or a group. The intervention *“Substance Use Treatment”* reflects the physical and psychosocial care of patients who have problems with alcohol or drugs, the intervention *“Suicide Prevention”* describes the nursing procedure to prevent suicide, and the intervention *“Teaching: Procedure / Treatment”* is defined as the procedure of teaching patients to understand the steps of the treatment. The remaining 30 NIC interventions contained only one or two actions. Their contents were very different and there was no obvious pattern that explained the nature of these interventions.

Statements unable to be mapped to NIC

Twenty-two actions did not fit existing NIC interventions due to their meaning and descriptions and required the creation of additional NIC interventions, or the revision of some structures in the NIC taxonomy. These actions are grouped into eight interventions by consensus of the authors considering context, aims and intention described in articles (Table 3).

Table 3: Overview of non-mapped statements and suggestions for creating additional interventions and their classification in the taxonomy of NIC

| NIC Intervention / Code (Domaines, Classes) | N | Actions: Text passages specifying the actions |
|--|---|--|
| Care Planning 6 (Y) | 5 | The individualization of care plans / to involve the patient in care planning / to monitor patient progress in response to treatment / mapping out the situation together with the patient: <i>"The nurses collected information in order to gain a holistic view of the patient's life and tried to be sensitive about the meaning of what the patient said. It was essential for the patient to narrate his or her own history and describe the kind of help that was most needed"</i> (Wadell & Skärsäter, 2007). / Involving in drawing up their own care plans: <i>"This process should not only include service users reading and signing their care plans together with staff, or service users discussing the progress of this care to determine whether or not the care plan is meeting their needs, but also service users actually devising care plans in partnership with staff"</i> (Richards et al. 2005). |
| Therapy 3 (?) | 5 | Cognitive behavioral therapy / therapeutic interventions such as CBT / identification and provision of relevant therapeutic activities / solution-focused therapy: <i>"The focus of discussion is on solutions (not problems); the future (not the past) and on what's going well (rather than what's gone wrong)"</i> (Hosany et al. 2007). / Cognitive Behavior Therapy: <i>"Nurses are increasingly using cognitive behavior therapy as an intervention for psychological problems attached to a variety of clinical conditions"</i> (Macinnes, 2006). |
| De-escalation; 4 (V) | 4 | Talking with an aggressive patient / intervening in a patient–patient interaction / verbal de-escalation / de-escalation: <i>"P.r.n. medication should not be the first line of action, but is the treatment strategy when other less invasive interventions such as de-escalation, talking, or separation from the group are unsuccessful. De-escalation skills refer to a combination of understanding environmental reasons for aggression, risk assessment, and verbal and non-verbal</i> |

| | | |
|---|----------|--|
| | | <i>strategies for calming a situation</i> " (Curtis et al. 2007). |
| Partnership; 3 (Q) | 4 | Negotiating boundaries of closeness-distance / partnership with the patient: <i>"a partnership between the patient and nurse is crucial to reach a beneficial therapeutic result. This partnership facilitates the patient's participation in planning care and treatment such as decisions about privileges she might receive and whether she may go for walks alone"</i> (Engqvist et al 2007) / Creating a relationship based on trust: <i>"The nurses believed that the creation of a trusting relationship with the patient and ensuring that the patient has confidence in the care received was most important". "The nurses were aware that if they gave the patients time, built up their confidence, and entered into a trusting relationship with them, their patients would become more open and talk about their drinking habits"</i> (Wadell & Skärsäter, 2007) / developing a working relationship with the patient in everyday care giving: <i>"The texts revealed two main approaches in the nurse - patient relationship. The first and dominating approach emphasized the nurse as an "expert" knowing what was the best solution to the patients' problems or needs. The other approach emphasized the nurse as a "Collaborator" on the basis of mutual co-operation in exploring the patients' problems and needs"</i> (Berg & Hallberg, 2000). |
| Body Search; 4 (V) | 1 | Intimate safety searches (body safety searches). |
| Administration; 6 (b) | 1 | Administration: <i>"Ward based (general administration / checking post, staff training & supervision, staff rotation / collaboration"</i> (Bee et al. 2006). |
| Self Advocacy; 3 (Q) | 1 | Promote self advocacy and independent advocacy (developing personal autonomy). |
| Risk Identification: Aggression; 4 (V) | 1 | To make a judgment about a patient's potential to cause serious bodily harm to self or others. |

Five actions represented each of the most frequently identified interventions that focus on planning nursing care or therapies performed by nurses. The second most frequently identified interventions were each constituted by four actions that focus on de-escalation or partnership. The remaining interventions (Body Search, Administration, Self Advocacy or Risk Identification: Aggression) were represented by one action each.

Discussion

Various authors describe the content of nursing in psychiatric inpatient settings. Sauter et al. (2011) define the aims of psychiatric inpatient settings as a) prevention of danger, b) reduction of psychiatric symptoms, and c) improvement of subjective conditions and general stabilization in the context of the mental illness. The safe and structured environment of a psychiatric inpatient setting is essential for patients in need of protection from suicidal ideation, aggressive impulses, medication adjustment and monitoring, crisis stabilization, substance abuse detoxification, and behavior modification (Jordan Halter, 2009). Rungapadiachy, Madill & Gough (2004) identified mental health nurses as: an administrator who organizes, documents and links patients with other members of the health care team; an advocate of psychological interventions who spends time and builds relationships with patients as well as performs structured therapeutic programs (e.g. cognitive behavior therapy); an agent of physical interventions who observes and performs physical care (e.g. physical hygiene, nutritional needs); as well as an administrator of drugs and a teacher. Psychiatric mental health nurses assist patients in resolving mental, emotional and dysfunctional aspects of life crises. Nurses also manage and alleviate distressing symptoms of mental disorders, improve overall functioning, and decrease the consequences of mental illness (Holoday Worret, 2008).

Despite the fact that the results of the current literature search reflect all domains of the Nursing Interventions Classification (NIC), nursing care in inpatient psychiatric settings is represented by three main focuses. Around 75% of the identified interventions in the NIC domains are listed in the domains “*Safety*” (support against harm), “*Behavioral*” (supporting psychosocial functioning as well as facilitating lifestyle changes), and “*Health System*” (mediating between the patient and the health system).

Within the domain “*Safety*”, the class “*Risk Management*” contains the greatest number of interventions identified in the literature (40 statements). Based on these results, the work of psychiatric nurses in inpatient settings seems dominated by risk-reducing and risk-monitoring interventions. Buchanan-Barker & Barker (2005) interpreted the growing needs for safety as a main topic (of societies, the political mainstream as well as the mental health services) in the 21st century, influencing the medical paradigm within mental health care. However, the contemporary practices of mental health nurses are dominated by risk management activities, especially the “bureaucratic process of observation” (Buchanan-Barker & Barker, 2005). As an alternative to the concept of “*Risk Management*”, the authors suggest a concept of ‘bridging’ on the basis of interpersonal relationships and the power of caring.

The interventions in the domain “*Behavioral*” were distributed into different NIC classes. Two classes are particularly noteworthy: “*Coping Assistance*” (13 statements) and “*Patient Education*” (11 statements). The first class describes interventions of assistance in developing personal strengths, to adapt to functional changes and/or to achieve higher functional levels. Koivisto et al. (2004) describe experiences of patients with psychoses who received the help of nurses in inpatient settings. Generally, patients experience nursing care as helpful but unstructured. On the one hand, nursing interventions should protect patients from vulnerability so that the individual feels safe, understood, respected, and trusted

and thus becomes more self-conscious and maintains his or her integrity. On the other, nursing care should assist in the restructuring and empowering of the self to cope in daily life. Conversations with primary nurses are considered by many patients to be the most important caring activities (Koivisto et al, 2004). The class *“Patient Education”* contains interventions to facilitate learning. An earlier study has shown that patient education has to be a systematic and planned process, employing different educational methods and taking the interaction between patient and nurse into consideration (Hätönen et al, 2010).

The class *“Health System Mediation”* – integrated into the domain *“Health System”* – is the second most frequently represented class (18 nominations). The class contains interventions such as *“Admission Care”*, *“Discharge Planning”*, *“Case Management”* and *“Patient Rights Protection”*. It summarizes interventions that facilitate the interface between patients, their families and the health care system. These interventions seem particularly important because psychiatric inpatient settings are environments over which patients have little control (Roger & Gray 2009)

The class *“Drug Management”* (11 statements) contains interventions to facilitate desired effects of medical treatments. Effective medication management practices empower the patient to make informed treatment decisions and to closely monitor the effects of medicine (Gray & Deborah, 2009). In the current study, the class is represented by the interventions *“Medical Administration”* and *“Teaching: Prescribed Medication”*. The intervention *“Medical Administration”* is noteworthy as it is the most frequently cited nursing intervention in the current study. Tentative interpretations of this finding could include the legal necessity to meticulously document the administration of medication or the predominance of the medical paradigm in psychiatric nursing.

Although the greatest number of identified intervention terms and definitions are already contained in the NIC, the significance, meaning and content of some

interventions could not be mapped to the classification. Several actions describe different steps and approaches of planning nursing care focusing on individualization, on interactions between nurse and patient and on the process of monitoring. Although the NIC intervention *“Admission Care”* contains elements of statements found in the articles, it fails to define the comprehensive and accurate process of nursing care planning that seems to be a continual process throughout the whole period of hospitalization and not only at admission. Therefore the intervention *“Care Planning”* was suggested to accommodate the identified actions. Because the intervention *“Care Planning”* supports the effective use of nursing care, it should probably be listed in the domain *“Health System”*. Further, since the intervention refers to an interactive action between patient and nurse we propose its allocation to the class *“Health System Mediation”*.

This study revealed actions indicating different therapy methods performed by nurses in inpatient psychiatry. The NIC taxonomy contains two classes into which therapeutic nursing interventions in inpatient psychiatry can be allocated: *“Behavior Therapy”*, which contains interventions to modify behavior, and *“Cognitive Therapy”*, which contains interventions to support cognitive functioning. The design of the NIC taxonomy allows neither interventions with other therapeutic orientations (e.g. solution therapy) nor interventions with a combination of both approaches (e.g. cognitive behavior therapy) to be established. To ensure a comprehensive intervention classification system, it seems necessary to re-organize the current NIC taxonomy at the level of classes within the domain *“Behavioral”* to include further therapeutic approaches.

Several results found in the articles indicate the existence of nursing activities aiming to defuse foreseeable conflicts. The main focus of these activities is on de-escalating strategies to prevent different forms of aggression escalation and dangerous moments. These activities reduce the risks of harm and help control

circumstances. Pavalonis (2008) describes de-escalation skills as effective techniques in interpersonal relationships that are essential for mental health nurses. Further, Varcarolis & Alvarez (2009) mentioned that nurses have to be well-trained in de-escalation techniques to deal with violent situations and individuals. Because these nursing actions support safety, the suggested intervention *“De-escalation”* should be integrated into the domain *“Safety”* and into the class *“Risk Management”*.

The analysis of the articles highlighted actions that describe the importance of and different approaches to developing a partnership or working relationship with patients. In contrast to the NIC intervention *“Complex Relationship Building”*, which addresses the promotion of insight and behavioral changes, the actions found address successful interaction with patients, acting as a basis for nursing care and going beyond the necessity to promote insight and behavioral changes. The suggested intervention *“Partnership”* contains steps and approaches to establish a common basis for successful interaction between nurses and patients. The intervention *“Partnership”* requires time, professional skills and human resources and should be integrated into the domain *“Behavioral”* and the class *“Communication Enhancement”*.

The following interventions – reflecting nursing actions that are time consuming, contain several working steps, and have a beginning and an end – were identified in the literature by one statement only. Although their database seems to be marginal, the suggested interventions *“Body Search”* and *“Administration”* as well as *“Self Advocacy”* and *“Risk Identification: Aggression”* are well-established practical nursing activities in adult inpatient psychiatry but inadequately reflected in the literature.

The intervention *“Body Search”* is planned to be listed under the domain *“Safety”* and added to the class *“Risk Management”*. This intervention entails nurses searching for objects or substances that are not allowed in a certain area because

they are dangerous for others or for the patient him/herself. Based on the descriptions found, the intervention *“Administration”* contains common and regularly performed ward-based administrative actions unlinked to other interventions or to the NIC intervention *“Documentation”*. In this sense, *“administration”* was used to describe documentation and is therefore part of communication. For this reason, this new intervention should be listed under the domain *“Health System”* and the class *“Information Management”*. The suggested intervention *“Self Advocacy”* includes nursing actions that develop the personal autonomy of patients. The content of the suggested intervention *“Risk Identification: Aggression”* seems to be different from the content of the existing intervention *“Surveillance: Safety”*. The definition of *“Risk Identification: Aggression”* as a separate intervention, focusing on the identification of risk factors, seems to be more appropriate.

Limitations

Some limitations of this study should be mentioned. The search strategy was limited to German and English papers listed in the databases MedLine, PsychInfo, Cochrane and CINAHL, and explored articles published in English only. For this reason, language bias cannot be ruled out. The search strategy addressed publications listed in databases, while other written documents were excluded from the analyses. There is thus a need to encompass other languages and other kinds of publications (e.g. articles from related disciplines) as well as to extend research on alternative methodologies and samples (e.g. documentation analyses, interviews) regarding psychiatric nursing interventions.

The determination process of nursing interventions implies some room for interpretation, on the one hand by a lack of standardized language or precise description of actions in articles, and on the other in the course of assignment of actions at the abstraction level of activities to corresponding NIC interventions. The

consideration of contexts, aims and intentions of the identified actions in the original text limited the room for interpretation and entailed a decisive focus that allowed a precise assignment to interventions.

The identification of some psychiatric nursing interventions was based on one study only. Although these nursing interventions are established in practice and often used in the daily routine of psychiatric nursing, they are seldom described in the literature. Therefore, further research is needed to verify the present results. Additional studies are important to define psychiatric inpatient nursing care and to differentiate individual nursing interventions and activities.

Conclusion

This study demonstrates that nursing care in adult inpatient psychiatry settings is based on well-defined tasks and activities included in the Nursing Interventions Classification (NIC). About 83% of the statements (terms and definitions) found in the articles are contained by the classification. Nevertheless, there is still a necessity to specify and communicate some psychiatric nursing interventions. The results of this study provide a basis for further research on nursing interventions improving patient outcomes. The design of this study included a literature review and mapping procedures. It demonstrates that the NIC classification contains most activities and interventions described in the literature. Only a few interventions need to be added to the NIC classification or demand a reorganization of the taxonomy. Closing this gap would strengthen the knowledge base of mental health nursing as well as the application of the NIC classification in psychiatric nursing practice. It is essential that nurses understand why and through which activities they perform interventions.
